Units

c	3.00e8 m/s	**1 nm**	1e-9 m
h	6.63e-34 J·s	**1 MHz**	1e6 Hz
m_e	9.11e-31 kg	**1 Hz**	1/s
N_A	6.022e23	**1 amu**	1.661e-27 kg

Trend	→ across period	↓ down group
Z_{eff}	increases	~constant
Atomic radius	decreases	increases
Ionization energy	increases	decreases
Electron affinity	more favorable	less favorable

- Aufbau: 1s 2s 2p 3s 3p **4s 3d** 4p 5s 4d 5p 6s 4f 5d
- Capacity **s2 p6 d10 f14** · orbitals **s1 p3 d5 f7**

(1) EM Spectrum

Ranges	γ	X	UV	vis	IR	μw	radio
Frequency (v)	↑						↓
Energy (E)	↑						↓
Wavelength (λ)	<0.01	0.01–10	10–400	400–700	700–1e6	1e6–1e9	>1e9

- **vis** (violet · blue · green · yellow · orange · red)

(2) c = λv (Speed of light = wavelength × frequency)

λ ↓ / v →	Hz	kHz	MHz	GHz
m	3.00e8 (m/s)	3.00e5 (m·kHz)	3.00e2 (m·MHz)	3.00e-1 (m·GHz)
nm	3.00e17 (nm·Hz)	3.00e14 (nm·kHz)	3.00e11 (nm·MHz)	3.00e8 (nm·GHz)

(3) E = hv = h (c/λ) (Energy = Planck × frequency)

E ↓ / λ, v →	λ (m)	λ (nm)	v (Hz)
J / photon	1.9864e-25 / λ (J·m)	1.9864e-16 / λ (J·nm)	6.626e-34 × v (J·s)
J / mol	1.1962e-1 / λ (J·m/mol)	1.1962e8 / λ (J·nm/mol)	3.9902e-10 × v (J·s/mol)
kJ / mol	1.1962e-4 / λ (kJ·m/mol)	1.1962e5 / λ (kJ·nm/mol)	3.9902e-13 × v (kJ·s/mol)

- Grams → mol → ×6.022e23 for photon **count**

(4) Quantum Principles

Planck	Energy emitted only in fixed amounts (quanta)
Einstein	Light arrives in packets (photons) of fixed energy
Heisenberg	Position and velocity not both knowable
Bohr	e^- occupy fixed energy levels; explains line spectra

- Orbital = **region where an e^- is most likely found**
- $E = h\nu = h(c/\lambda) = R(1/n_f^2 - 1/n_i^2)$
- $n_i = \sqrt{1/(1/n_f^2 - hc/(R\lambda))}$; $n_f = \sqrt{1/(1/n_i^2 + hc/(R\lambda))}$

Variable	Value	Variable	Value
c	2.9979e8 m/s	h	6.626e-34 J·s
R	2.18e-18 J	hc	1.9864e-25 J·m
h/R	3.0394e-16 s	hc/R	9.1120e-8 m

(5) de Broglie

$$\lambda = h/(mu)$$

1. m → kg: g ×1e-3, amu ×1.661e-27
2. u → m/s: km/s ×1e3
3. λ = h/(mu)

- Answer is in m; ×1e9 for nm

(6) Electron Configuration

1. Fill in Aufbau order (see Units)
2. Respect **s2 p6 d10 f14**
3. Apply the exceptions

- **Cr = [Ar]$4s^1 3d^5$ · Cu = [Ar]$4s^1 3d^{10}$** (half/full d wins)
- Impossible if any subshell is over-filled ($3s^3$, $2p^8$)
- Faster than writing Aufbau: read it off the table — s-block (gp 1–2) → ns, p-block (13–18) → np, d-block → (n−1)d; the period number is n
- Can be a transition metal; ground state only

(7) Reading an Electron Configuration

Paramagnetic vs diamagnetic

1. Draw boxes for the outer subshell — **s 1 · p 3 · d 5 · f 7**
2. Fill singly, parallel spins, before pairing (Hund)
3. Count unpaired e^-

- Any unpaired → **paramagnetic** · all paired → **diamagnetic**
- Full subshells (s^2, p^6, d^{10}) are always paired

Excited vs ground state

- **Ground** = strict Aufbau order, no gaps
- **Excited** = an e^- sits higher than Aufbau requires, leaving a **gap below it**; same total e^- count

Valence electrons

- Count e^- in the **highest n** (outer s + p) = the group number, 1A→1 … 8A→8
- Everything below the highest n is **core**

(8) Ion Configuration

1. Start from the neutral atom
2. **Anion:** add e^- into the outer p until it reaches a noble-gas configuration
3. **Cation:** remove from the **highest n first**

- Transition metals lose **4s before 3d**
- Exam ions are main-group, not transition metals

(9) Penetration, Pauli & Shielding

- **Penetration** — an orbital reaching into the core region is less shielded, so it sits at **lower energy**. Within a shell **s < p < d < f**
- **Pauli exclusion** — no two e^- carry the same four quantum numbers → 2 per orbital, opposite spins
- **Shielding** — only **core** (inner) e^- shield effectively; valence e^- shield each other poorly

(10) Z_{eff} & Core Electrons

$$Z_{eff} \approx Z - (\text{core } e^-)$$

1. Core e^- = total e^- − valence e^- (= the **previous noble gas**)
2. $Z_{eff} \approx Z - \text{core } e^-$

- Same period → same core, so the **rightmost** element wins
- Poor valence shielding is why Z_{eff} rises across a period

(11) Rank Atomic Size

- Down a group **bigger** (new shell) · across a period **smaller** (Z_{eff} pulls in)
- **↑ = lower-left · ↓ = upper-right**
- Group position beats period position when both apply
- cation < neutral < anion

(12) Rank Ionization Energy

- Across a period ↑ · down a group ↓ (opposite of radius)
- **↑ = upper-right** (He ↑ of all) · **↓ = lower-left**
- $IE_2 > IE_1$ always
- **Big jump** appears once the first **core** e^- is removed

(13) Rank Electron Affinity

- **Most eager for an e^- = halogens, upper right** — this course writes it both as "most negative EA" and "largest positive EA"; either phrasing means the same element
- Noble gases and full/half-full subshells ≈ 0 or unfavorable
- **EA(X) and IE of X^- are the same magnitude** — F + e^- releases exactly what F^- → F costs

(14) Families & Diagonal Rule

1A	alkali metals	most reactive metals; ↑ **down**
2A	alkaline earth	reactive, less than 1A
7A	halogens	reactive nonmetals; ↓ **down**
8A	noble gases	**inert** — full octet

- **Diagonal rule** — an element resembles its down-right neighbor: Li~Mg · **Be~Al** · B~Si

HW-only gaps — off the exam list

Oxides — metal oxide = **basic** (K_2O, MgO, Fe_2O_3, Cr_2O_3) · nonmetal oxide = **acidic** (P_4O_{10}, SO_2, CO_2, Cl_2O_7) · Al_2O_3 and BeO = **amphoteric**

Formula from charges — 1A 1+ · 2A 2+ · 3A 3+ · 5A 3− · 6A 2− · 7A 1−; criss-cross and reduce

- Same-group swap keeps the pattern: BaS → **CaO**
- 2A + $3F_2$ → $2AF_3$ ⇒ A is 3+ (**Al**) · 3Li + Z → Li_3Z ⇒ Z is 3−, so Mg gives $\mathbf{Mg_3Z_2}$

Bond-type ID — ionic **and** covalent together = a salt of a **polyatomic ion** (NH_4NO_3, K_2SO_4); all-nonmetal = covalent only

Family reactions

- $2K(s) + 2H_2O(l) \rightarrow 2KOH(aq) + H_2(g)$
- $H_2(g) + Cl_2(g) \rightarrow 2HCl(g)$

Odds & ends

- Lanthanides = 4f row (**Ce**) · actinides = 5f (U)
- Diatomic: H_2 N_2 O_2 F_2 Cl_2 Br_2 I_2
- Metallic character ↑ down, ↓ across → **lower-left** wins
- Isoelectronic = matches a noble gas e^- count (K^+, Cl^-, Ca^{2+} = Ar)

(15) Lattice Energy

Energy **released** when gaseous ions form the solid crystal.

$$U \propto \frac{q_1 q_2}{r_1 + r_2}$$

1. Compare charges first
2. If charges tie, smaller ions win

- ↑ charge → ↑ **U** (dominant) · ↑ ionic radius → ↓ U

(16) Electronegativity

EN = an atom's ability to attract the electrons shared in a bond.

$$\Delta EN = |EN_A - EN_B|$$

- Read EN off the chart — EN ↑ up and to the right, F highest, noble gases excluded

(17) Bond Polarity

1. Take the absolute difference (ΔEN)
2. Classify

~0	nonpolar covalent
0.4 – 1.9	polar covalent
≥ 2.0	ionic

- **"Most polar"** → **ΔEN alone** (largest difference wins)
- **"Strongest / shortest bond"** → **bond order FIRST:** triple > double > single. ΔEN only breaks ties between equal orders — a C≡N beats a high-ΔEN Si=O
- Larger ΔEN → stronger, shorter bond, but the guide flags this as *not always true*

(18) Formal Charge & Resonance

$$FC = (\text{valence } e^-) - [\text{nonbonding } e^- + \#\,\text{bonds}]$$

1. FC on every atom
2. Check ΣFC = the overall charge
3. Pick the structure with FCs **nearest 0**
4. Put any −1 on the **more electronegative** atom

- Equivalent resonance forms → real bonds are the **average** (e.g. 1½)

(19) Lewis Structures ×4

1. Total valence e^- — **+**1 per negative charge, **−**1 per positive
2. Central atom = least electronegative, never H
3. Single bonds out to every atom
4. Fill outer octets with lone pairs (H takes 2)
5. Leftover e^- onto the central atom
6. Central below 8 → pull an outer lone pair into a double/triple bond, **unless** Al/B/Be
7. Check formal charges — see (18)

Four structures — one of each type:

(a) Normal octet	8 valence e^- per atom (H wants 2) — H_2O, CH_4, NH_3, CO_2, CH_2Cl_2, CH_3CH_2Cl
(b) Incomplete octet	**Al, B, Be only** — content below 8, do not add double bonds to fix. BF_3/BCl_3/AlI_3 leave 6 e^- on the center; $BeCl_2$ leaves 4
(c) Expanded octet	Central atom **period 3 or below** (S, P, Cl, Xe, As, I) uses empty d orbitals for >8 — $AsCl_5$, XeI_2, SO_4^{2-}
(d) Organic	**–OH** alcohol · **C=O** aldehyde/ketone · **–COOH** carboxylic acid · $\mathbf{-NH_2}$ amine

- Every C makes 4 bonds; a –COOH carbon carries one **=O** and one **–O–H**; every O gets 2 lone pairs
- Ions go in brackets with the charge outside
- If the all-single-bond form leaves the center with a nonzero FC, add double bonds to zero it (e.g. two S=O in SO_4^{2-})

(20) Photoelectric Effect

$$KE = h\nu - \Phi = \frac{1}{2}mu^2$$

1. E_{photon} = hv = hc/λ
2. KE = E_{photon} − Φ
3. Speed: u = √(2·KE/m_e)
4. Threshold (KE = 0): λ = hc/Φ

- Φ (also written **W**) = work function = minimum energy to eject an e^-
- Given a threshold λ instead of Φ: Φ = hc/ $\lambda_{threshold}$
- × N_A for a per-mole binding energy
- ↑ **λ** ⇄ ↓ **v** ⇄ threshold

(21) Heisenberg Uncertainty

$$\Delta x \cdot \Delta p \geq \frac{h}{4\pi}, \quad \Delta p = m\Delta u$$

1. Δp = m·Δu (kg, m/s)
2. Δx ≥ h/(4π·Δp)

- Result is the **minimum** uncertainty
- Rearrange the same way to solve for Δu
- Keep everything in kg, m, s

(22) Born–Haber Cycle

$$\Delta H^\circ{}_f = \Delta H_{sub} + \Sigma IE + \frac{1}{2}BE + EA + U$$

1. List every step with its sign: sublimation (+), IE (+), bond dissociation (+), EA (usually −), U (−)
2. **Halve** the bond dissociation if you need only one atom
3. Chain: elements → gaseous atoms → gaseous ions → solid
4. Set the chain equal to $\Delta H^\circ{}_f$
5. Solve for the single unknown

- Use IE_2 as well when the cation is 2+
- U runs ions(g) → solid, so it comes out **negative**; report |U| if asked for a positive lattice energy

(23) Bond Enthalpy

$$\Delta H_{rxn} = \Sigma\Delta H(\text{bonds broken}) - \Sigma\Delta H(\text{bonds formed})$$

1. List bonds broken (reactants) and formed (products), using the balanced coefficients
2. Σ BE(broken), always positive
3. Σ BE(formed), subtracted
4. ΔH = Σ broken − Σ formed

- Bonds unchanged on both sides cancel — skip them
- Negative ΔH = exothermic
- For "heat released by *g* of X," convert g → mol and scale
